# Information Retrieval Course, Final Project, Search Engine

a. Shoham Choclin, 322482837, shoamch@post.bgu.ac.il

b. Aviel Yitzhak, 316126598, avielyi@post.bgu.ac.il

c. Link to a Github: https://github.com/choclinsh/irProjectShohamAviel
d. Link to a Google Storage Bucket: https://storage.googleapis.com/bucket3224/

If that dont work, this is the url:
https://console.cloud.google.com/storage/browser/bucket3224?organizationId=536124907474&project=info-retrieval-project-480012

e. Key experiments:

We ran our experiments based on the train queries provided by the course team.

In our initial implementation, the search engine was designed to retrieve document titles individually. For every document in the results list (potentially hundreds per query), the system opened a new connection to the SQLite database, fetched the title, and closed the connection.
Key Findings:

Zero Quality: The system yielded an Average Quality of 0.0000.

High Overhead: Despite reporting "Successful" execution (no server crashes, just timeouts), the Average Latency was 17.67s. Just 2 queries were not timeouted, and even they were not successful at all.
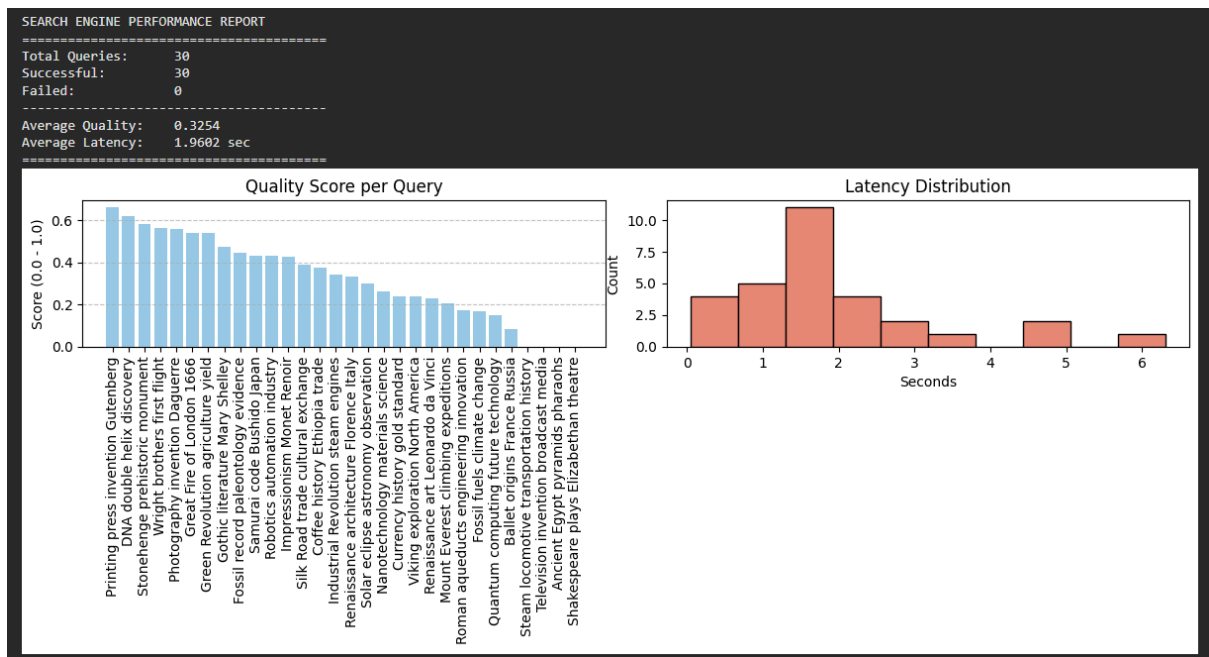

Analysis: The 0.0 quality score indicates a functional failure despite the code technically running. The overhead of opening and closing thousands of database connections caused internal timeouts or resource exhaustion (file handle limits), leading the system to return empty results or "Title Not Found" placeholders for every document.

```
===================================
SEARCH ENGINE PERFORMANCE REPORT
===================================
Total Queries:     30
Successful:        2
Failed:            28
-----------------------------------
Average Quality:   0.0000
Average Latency:   17.6725 sec
===================================
```
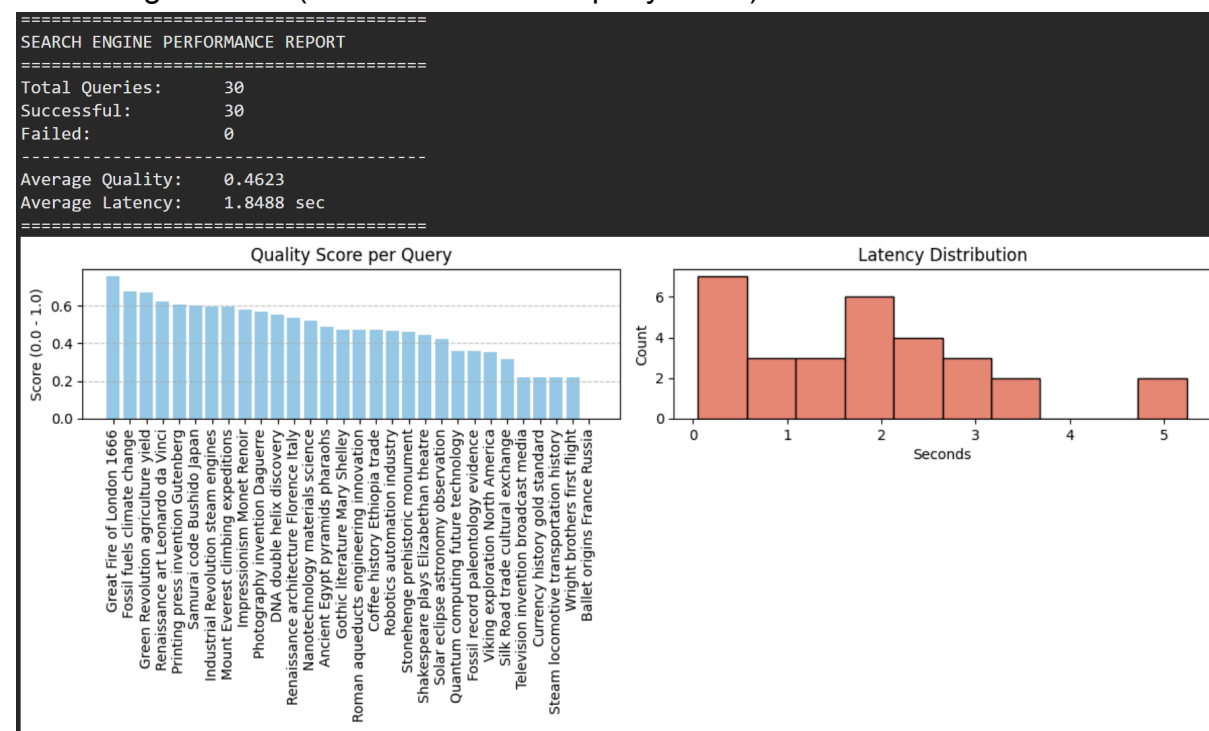

Next we fixed the individual database connection and upgraded it to fetching the titles in batches in smaller sizes than the sql threshold. We saw a great decrease in efficiency (average latency of 2.4s) and no query timeouted but quality still very low.

```
SEARCH ENGINE PERFORMANCE REPORT
=========================================
Total Queries:     30
Successful:        30
Failed:            0
-----------------------------------------
Average Quality:   0.0000
Average Latency:   2.4085 sec
=========================================
```
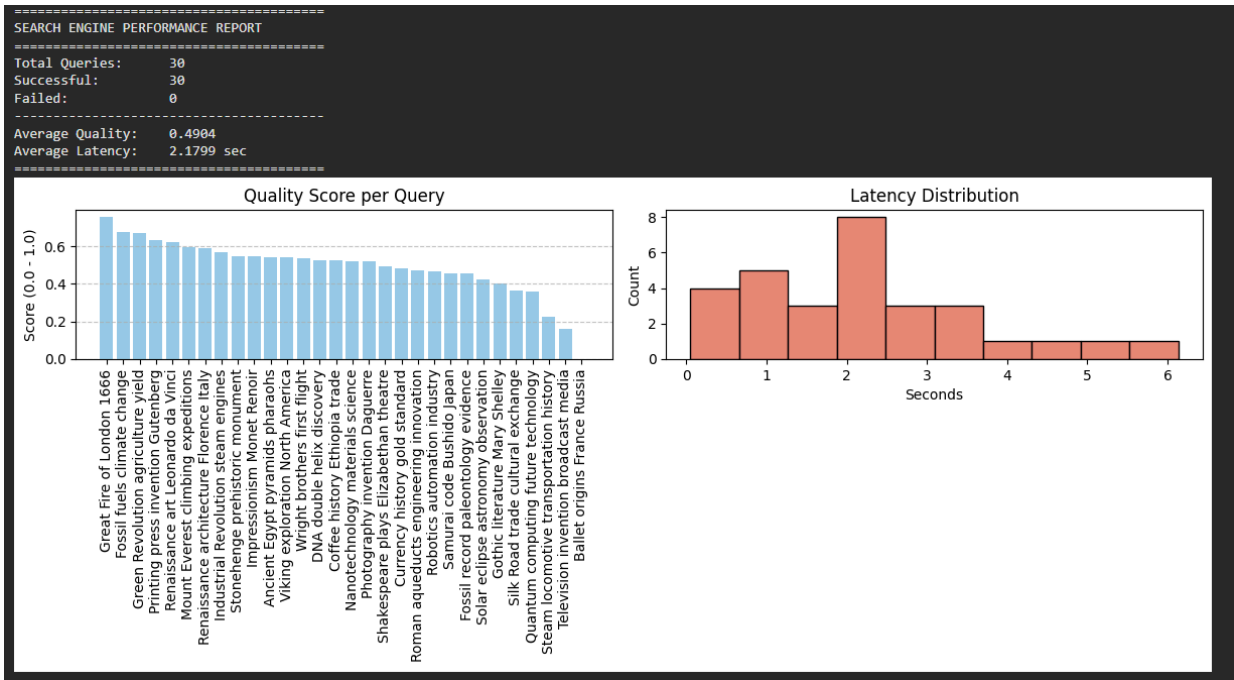

In order to increase the quality we made several steps which improved our performance: in order to compute the cosine similarity matrix for the whole vocabulary like in assignment 3, we computed only for the valid terms in the single query. In addition, we only saved the postings list of terms in the query instead of iterating over redundant unnecessary postings lists.

SEARCH ENGINE PERFORMANCE REPORT
========================================
Total Queries:      30
Successful:         30
Failed:             0
----------------------------------------
Average Quality:    0.3254
Average Latency:    1.9602 sec
========================================

We tried using bm25 on the body index instead of cosine similarity and it worked. It indeed Improved the performance by a lot while maintaining low latency. In addition we ignored postings list of terms with low idf score due to little contribution for the final score. We made the search function threadable, as the searching on the three parts of search happens in parallel instead of sequentially. (Search on body title and anchor). Moreover, we changed the weights of the score from each part to favor the title score. We normalized it because the bm25 scores are larger than the title and anchor logic scores (of distinct words of query count).

========================================
SEARCH ENGINE PERFORMANCE REPORT
========================================
Total Queries:      30
Successful:         30
Failed:             0
----------------------------------------
Average Quality:    0.4623
Average Latency:    1.8488 sec
========================================

In the last experiment we added pageview data and multiplied the scores calculated in the previous experiment with a smoothed pageview contribution (increased the rating of pages with high views. That brought us to the final state of our search engine with average latency of 2.17 seconds and average quality of 0.49. It made it a little slower than the previous but we compromised to increase the quality even more.

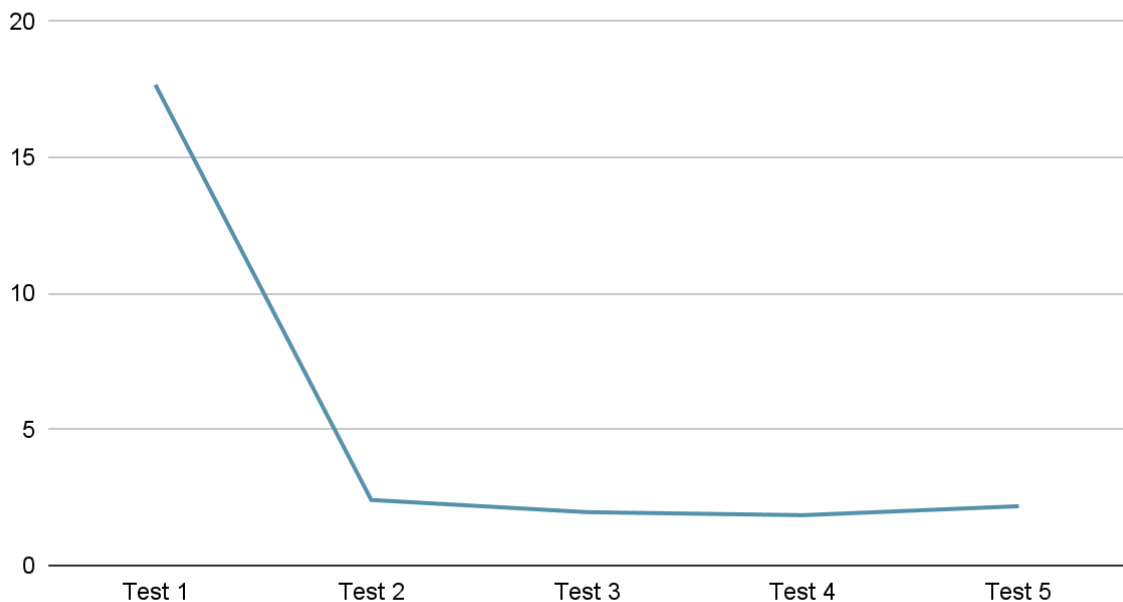

f.

## Quality Performance

g.

## Average Latency

We can see nice improvement in both measures while we dealt with the project over time and researched different techniques and tricks. (Both decrease in latency and relative improvement of precision)

h.

```
Detailed Results (Sorted by Worst Performing):
                                      Query  Duration  Score

 1                Great Fire of London 1666  5.380514  0.756
```

We divide the explanation into 2 scenarios:

Successful Query Analysis:

Query: `Great Fire of London 1666` Performance: Score 0.756 (Highest ranked result) Duration: 5.38s

What worked well: The engine performed exceptionally well here because the query contains highly specific named entities ("Great Fire", "London") and a unique temporal indicator ("1666").

Title/Anchor Weighting: Our scoring system places a heavy combined weight (0.7) on Title and Anchor matches. Since "Great Fire of London" is likely an exact title match, the engine correctly identified the core document immediately.

Specific Term Frequency: The term "1666" is rare in the corpus compared to generic words. In our BM25 calculation, rare terms generate a high IDF (Inverse Document Frequency) value, ensuring that documents containing this specific year were ranked significantly higher than generic pages about "London" or "Fire".

2. Poor Query Analysis

Query: `Ballet origins France Russia` Performance: Score 0.000 (Lowest ranked result) Duration: 3.10s

What didn't work: As noted in our analysis, the top results were irrelevant broad topics: `["25391", "Russia"]` and `["1592", "Alexander III of Russia"]`. The engine failed to capture the *intersection* of the concepts; it instead retrieved documents heavily focused on just one of the query terms ("Russia").

Dominant Factor: The PageView Multiplier & Lack of Conjunctive Logic The failure here is driven by two mechanisms in our code:

Multiplicative PageView Boosting: The code multiplies the relevance score by the PageView score: `score * pv_scores.get(doc_id, 1)`. The article for "Russia" is extremely popular and has a massive PageView score. Even if the textual similarity for "Ballet" was low, the sheer popularity of the "Russia" page multiplied its score enough to push it to the #1 spot.

"OR" Logic over "AND" Logic: The search logic (`search_body_logic_scores` and BM25) adds up scores for any matching word. It does not enforce that *all* words must be present. Since the document "Russia" likely contains the word "Russia" dozens of times, it accumulated a high BM25 score for that single term, overpowering the missing term "Ballet."

What can be done about it (Corrective Actions):

Dampen Popularity Impact: We should change the PageView boosting from a multiplicative factor to an additive one (or use a significantly smaller log-base), so that popularity acts only as a tie-breaker rather than a dominant ranking factor.

Enforce Conjunctive Search (AND): We can modify `search_body_logic` to penalize or filter out documents that do not contain a minimum percentage of the query terms (e.g., a document *must* contain both "Ballet" and "Russia" to be considered).

Identify Focus Terms: Implement logic to identify the "rarest" word in the query (in this case, "Ballet") and mandate its presence, preventing broad terms like "France" or "Russia" from hijacking the results.

 In addition the engine dealt poorly with really long queries with many terms and a large number of page candidates. We can add a query words threshold that limit the number of query words, or set a limit to search over only the meaningful words in a long query.
